

BR 95 X

10/25/95

By comparing 94 E and 94 F (esp. F) w/ 95 X, we determined that 95 X starts just below the 1000 yr sand, with the base of which is at 104 cm in 94 F.

There was a wood chunk embedded in the alum pipe at top of 95 X which could not have been at 104 cm depth and ∴ must have been pushed down from near surface.

The pushing down of the wood disturbed the upper ~ 1 m, which then liquefied upon vibration.

New compaction estimates for 95 X using new vs old drive length:

old drive length = 657

new drive length = 657 - 104 = 553

% reduction in porosity = $\frac{\text{drive length} - (\text{recovered core length})}{\text{drive length}}$

% reduction in porosity = $\frac{553 - 553}{553} = \emptyset$

<u>old</u>	<u>new</u> (add 100)	<u>newer new</u>
0-156	100-256	45 - 201
156-276.5	256 - 376.5	201 - 321.5
276.5-431.5	376.5 - 531.5	321.5 - 476.5
431.5-556	531.5 - 656	476.5 - 601

1/26/95: we discovered a discontinuous 1-4 grain thick DE 2 sand in core X which made us rethink the depths. Because sneaker is just below this discont. DE 2 sand, we again compared 95X to 95 F, found several correlative gray laminae at the 50-60 cm level in 95 F, from which we now conclude that the top of 95 X is = 45 cm.
